Yoshida,2012-12-06 In the comparative physiology of photoreception by the Protista and the invertebrates two aspects are emphasized 1 the diversity of visual processes in these groups and 2 their bearing upon general mechanisms of photoreception Invertebrates have evolved a far greater variety of adaptations than vertebrates modifications aiding survival in the remarkably different biotopes they occupy The number of species in itself suggests this multiformity each of them has peculiarities of its own in morphology as well as in physiology and behavior But these special adaptations are variations on a few great themes Although the catalogue of invertebrate species is immense the literature concerning them nearly rivals it in extent even if one considers only that fraction dealing with visual physiology Taxonomy proceeds by grouping the species categorizing them in genera families orders and progressively larger units Similarly comparative physiology aims at an analogous more or less comprehensive

classification This Part A of Volume VII 6 like Part B that follows it emphasizes the broad questions that concern groups larger than the individual species in some cases these questions have general applicability The middle course between approaches that are too specialized and those that are too general is often elusive but here we attempt to follow it The vast number of special adaptations probably as we have said as large as the number of species is beyond the range even of a handbook
