

Substances held together by covalent bonds are usually divided into two groups based on whether individual (distinct) molecules exist or not. In a *molecular solid*, individual molecules in the solid state are attracted to each other by relatively weak intermolecular forces between the molecules. *Covalent-network solids*, on the other hand, consist of atoms forming covalent bonds with each other in all directions. The result is an almost infinite network of strong covalent bonds—there are no individual molecules.

Covalent bonds may be classified as polar or nonpolar. The element chlorine, for example, exists as a diatomic molecule, Cl_2 . The two chlorine atoms are held together by a single covalent bond, with the two electrons in the bond equally shared between the two identical chlorine atoms. This type of bond is called a *nonpolar* covalent bond. The compound hydrogen chloride (HCl) consists of a hydrogen atom and a chlorine atom that also share a pair of electrons between them. Because the two atoms are different, however, the electrons in the bond are not equally shared between the atoms. Chlorine has a greater *electronegativity* than hydrogen—it attracts the bonding electrons more strongly than hydrogen. The covalent bond between hydrogen and chlorine is an example of a *polar* bond. The distribution of bonding electrons in a nonpolar versus polar bond is shown in Figure 2. Notice that the chlorine atom in HCl has a partial negative charge (δ^-) while the hydrogen atom has a partial positive charge (δ^+).

Figure 2. Nonpolar versus Polar Covalent Bonds.

The special properties of metals compared to nonmetals reflect their unique structure and bonding. Metals typically have a small number of valence electrons available for bonding. The valence electrons appear to be free to move among all of the metal atoms, which must exist therefore as positively charged cations. *Metallic bonding* describes the attractive forces that exist between closely packed metal cations and free-floating valence electrons in an extended three-dimensional structure.

Experiment Overview

The purpose of this experiment is to study the physical properties of common solids and to investigate the relationship between the type of bonding in a substance and its properties. The following physical properties will be studied:

- **Volatility and Odor:** Volatile substances evaporate easily and may have an odor.
- **Melting Point:** The temperature at which a solid turns into a liquid.
- **Solubility:** Ability of one substance to dissolve in another. Water is a highly polar solvent. Hexane is nonpolar.
- **Conductivity:** Ability to conduct electricity.
- **Hardness:** Resistance of a substance to being scratched.
- **Brittleness:** Tendency of a solid to break or crumble when a stress is applied.
