

BEAKS AS TOOLS: SELECTIVE ADVANTAGE IN CHANGING ENVIRONMENTS

INTRODUCTION

Peter and Rosemary Grant's pioneering work on the Galápagos Island finches has given us a unique insight into how species evolve over generations. The film *The Origin of Species: The Beak of the Finch* illustrates that some traits may enable an animal to find food or attract mates better than other individuals can. If beneficial traits like these have a genetic basis and can be passed on to future generations, we refer to them as **adaptations**, which are selected for by the environment through a process called **natural selection**. Beneficial traits increase an individual's fitness by allowing it to survive and ultimately produce more offspring than individuals without the traits. This can lead to evolution if, over time, these traits (and their associated genetic variants, or **alleles**) become more common in the population while unfavorable traits slowly disappear.

One crucial insight into how adaptation occurs came from the medium ground finch (*Geospiza fortis*). With its short, blunt beak, the medium ground finch is perfectly adapted to picking up seeds from the ground, although beak size varies slightly within medium ground finch populations. When food was plentiful and included different seed sizes, all ground finches were able to find food. However, when drought struck the small island of Daphne Major in 1977, the vegetation and the available seeds changed considerably, so that the finches now had to compete for food. When the smaller seeds disappeared, the finches had to turn to the much larger, spiny seeds that were hard to crack open. The smaller medium ground finches with slightly smaller beaks ran out of food. But finches that had slightly larger beaks could still forage on the much bigger, spiny seeds, which gave them a survival advantage.

Five years later, unusually long-lasting rainfalls allowed vines to overrun the island and again changed the vegetation drastically. The dominant slow-growing plants that produced large, tough seeds were replaced by fast-growing plants with smaller, softer seeds such as grasses and vines. When drought struck again two years later and birds had to compete for food, larger seeds were scarce. The birds with larger beaks now had difficulty picking up the more abundant small seeds produced by the vines and grasses. Therefore, selection swung in the opposite direction; more finches with smaller beaks survived, and their offspring inherited smaller beaks. Although the beak size difference itself was small, it made the difference between life and death during both droughts.

Darwin's finches.

Galápagos finches are adapted to living in habitats with strikingly different food sources, such as the cactus finch on the left and the medium ground finch on the right. Changes in beak shapes over time have enabled each finch species to find and manipulate the food that is most common in their habitat. (Photos courtesy of John Van de Graaff.)

This activity will demonstrate why a slight difference in beak size can significantly impact a bird's ability to survive. You will act as the finches and fight for survival by "eating" as many seeds as possible within the allotted time. You will use two different types of tools to represent different beak types to see which is best adapted to collect and "eat" food under different conditions. The activity exaggerates the differences in beak size to illustrate that a beak is like any other tool: You need the right tool for the right job.
