

**Key Idea:** Respiration is the process by which cells convert energy in glucose to usable energy, which is stored in the molecule ATP. The process uses oxygen, which can be quantified using a simple respirometer. A respirometer can be used to measure the amount of oxygen consumed by an organism during cellular respiration and so can be used to measure respiration rate. A simple respirometer is shown in the diagram below. The carbon

dioxide produced during respiration is absorbed by the potassium hydroxide. As the oxygen is used up, the coloured bubble in the glass tube moves. Measuring the movement of the bubble allows an estimation of the change in volume of gas and therefore the rate of cellular respiration. Various versions of these simple respirometers exist. You may use a set-up that uses micro respirometers, which are easy to construct and work quickly because of their small volumes.

### Investigation 9.2 Measuring respiration in germinating seeds

See appendix for equipment list.

Caution is required when handling potassium hydroxide as it is caustic and can cause chemical burns. You should wear protective eyewear and gloves.

1. Work in groups of four to set up three respirometers using the set-up shown right as a guide.
2. Collect three boiling tubes and place two cotton balls in the bottom of each. Label the vials 1, 2, and 3.
3. Use a dropper to add 15% potassium hydroxide (KOH) solution on the cotton balls until they are saturated (there should be no liquid in the boiling tube). Add the same amount of KOH to the cotton balls in each vial.
4. Place gauze on top of the cotton balls in each vial. This prevents the KOH coming into contact with the seeds and killing them.
5. Quarter fill vial 1 with glass beads made up to the same volume as in the other two vials. Determine the volumes using a water displacement method.
6. Quarter fill vial 2 with 25 germinated bean seeds. These seeds will be damp as they have been germinated under damp paper towels for four days.
7. Quarter fill vial 3 with the same number of non-germinating (dormant) seeds into vial 3 (making up the volume with glass beads).
8. Once the vials have been prepared, cap each vial with a stopper fitted with a 1 mL pipette, tip pointing outward. Add a weight (two metal washers) to each vial.
9. Use a dropper or fine pipette to place a drop of food colouring into the tip of each pipette to seal off the system.
10. Place all three respirometers in a 25°C water bath supported so that the pipette tips stay out of the water (see diagram right). Leave for 10 minutes to equilibrate.
11. After 10 minutes of equilibration, record the position of the food colouring bubble and start a timer.
12. The recorded movement of the coloured bubble in tube 1 (glass beads) account for any pressure fluctuations. Subtract the changes recorded in tube 1 in each of tube 2 and 3 to obtain the corrected volume changes caused by the use of oxygen.
13. Record your results on the table at the top of the next page.
