Gulati, Charles F. Hawkins, 2012-12-06 Power supply current monitoring to detect CMOS IC defects during production testing quietly laid down its roots in the mid 1970s Both Sandia Labs and RCA in the United States and Philips Labs in the Netherlands practiced this procedure on their CMOS ICs At that time this practice stemmed simply from an intuitive sense that CMOS ICs showing abnormal quiescent power supply current IDDQ contained defects Later this intuition was supported by data and analysis in the 1980s by Levi RACD Malaiya and Su SUNY Binghamton Soden and Hawkins Sandia Labs and the University of New Mexico Jacomino and co workers Laboratoire d'Automatique de Grenoble and Maly and co workers Carnegie Mellon University Interest in IDDQ testing has advanced beyond the data reported in the 1980s and is now focused on applications and evaluations involving larger volumes of ICs that improve quality beyond what can be achieved by previous conventional means In the conventional style of testing one attempts to propagate the logic states of the suspended nodes to primary outputs This is done for all or most nodes of the circuit For sequential circuits in particular the complexity of finding suitable tests is very high In comparison the IDDQ test does not observe the logic states but measures the

integrated current that leaks through all gates In other words it is like measuring a patient s temperature to determine the state of health Despite perceived advantages during the years that followed its initial announcements skepticism about the practicality of IDDQ testing prevailed The idea however provided a great opportunity to researchers New results on test generation fault simulation design for testability built in self test and diagnosis for this style of testing have since been reported After a decade of research we are definitely closer to practice
